

## Dual 50MHz Comparator/Pin Receiver

The EL2252 dual comparator replaces the traditional input buffer + attenuator +ECL comparator +ECL to TTL

translator circuit blocks used in digital equipment. The EL2252 provides a quick 7ns propagation delay while complying with  $\pm 10V$  inputs. Input accuracy and propagation delay is maintained even with input signal Slew Rates as great as  $4000V/\mu s$ . The EL2252 can run on supplies as low as -5.2V and +9V and comply with ECL and CMOS inputs, or use supplies as great as  $\pm 18V$  for much greater input range.

The EL2252 has a /TTL pin which, when grounded, restricts the output  $V_{OH}$  to a TTL swing to minimize propagation delay. When left open, the output  $V_{OH}$  increases to a valid CMOS level.

The comparators are well behaved and have little tendency to oscillate over a variety of input and output source and load impedances. They do not oscillate even when the inputs are held in the linear range of the device. To improve output stability in the presence of input noise, an internal 60mV of hysteresis is available by connecting the HYS pin to  $V_-$ .

Elantec's products and facilities comply with MIL-I-45208A, and other applicable quality specifications. For information on Elantec's processing, see Elantec document, QRA-1; "Elantec's Processing, Monolithic Integrated Circuits".

## Features

- Fast response — 7ns
- Inputs tolerate large overdrives with no speed nor bias current penalties
- Propagation delay is relatively constant with variations of input Slew Rate, overdrive, temperature, and supply voltage
- Output provides proper CMOS or TTL logic levels
- Hysteresis is available on-chip
- Large voltage gain —  $8000V/V$
- Not oscillation-prone
- Can detect 4ns glitches
- MIL-STD-883 Rev. C compliant

## Applications

- Pin receiver for automatic test equipment
- Data communications line receiver
- Frequency counter input
- Pulse squarer

## Ordering Information

## Applications Information

The EL2252 is very easy to use and is relatively oscillation-free, but a few items must be attended. The first is that both supplies should be bypassed closely. 1 $\mu$ F tantalums are very good and no additional smaller capacitors are necessary. The EL2252 requires  $V_-$  to be at least 5V to preserve AC performance.  $V_+$  must be at least 6V for a TTL output swing, 8V for CMOS outputs.

The input voltage range will be referred to the more positive of the two inputs. That is, bringing an input as negative as  $V_-$  will not cause problems; it's the other input's level that must be considered. The typical input range is +13/-12V when the supplies are  $\pm 15$ V. This range diminishes over temperature and varies with processing; it is wise to set power supplies such that  $V_+$  is 5V more positive than the most positive input signal and  $V_-$  more negative than 6V below the most negative input.  $\pm 12$ V supplies will easily encompass all CMOS and ECL logic inputs. If the input exceeds the device's common-mode input capability, the EL2252 propagation delay and input bias current will increase. Fault currents will occur with inputs a diode below  $V_-$  or above  $V_+$ . No damage nor  $V_{OS}$  shift will occur even when fault currents within the absolute maximum ratings.

One of the few ways in which oscillations can be induced is by connecting a high-Q reactive source impedance to the EL2252 inputs. Such sources are long wires and unterminated coaxial lines. The source impedance should be de-Q'ed. One method is to connect a series resistor to the EL2252 input of around 100 $\Omega$  value. More resistance will calm the system more effectively, but at the expense of

comparator response time. Another method is to install a "snubber" network from comparator input to ground. A snubber is a resistor in series with a small capacitor, around 100 $\Omega$  and 33pF. Each physical and electrical environment will require different treatments, although many need none.

The major use of the HYS pin is to suppress noise superimposed on the input signal. By shorting the HYS pin to  $V_-$  a  $\pm 30$ mV hysteresis is placed around the  $V_{OS}$  of the comparator input. Leaving the pin open, or more appropriately, grounding the HYS pin removes all hysteresis. Connecting a resistor between HYS and  $V_-$  allows an adjustment of the peak-to-peak hysteresis level. Unfortunately, an external resistor cannot track the internal devices properly, so temperature and unit-to-unit variations of hysteresis are increased. The relationship between the resistor and resulting hysteresis level is not linear, but a 1.5k resistor will approximately halve the nominal value.

The time delay of the EL2252 will increase by about 0.7ns when using full hysteresis.

The EL2252 is specifically designed to be tolerant of large inputs. It will exhibit very much increased delay times for input overdrives below 100mV. If very small overdrives must be sensed, the EL2018 or EL2019 comparators would be good choices, although they lose accuracies with signal input Slew Rates above 400V/ $\mu$ s. The EL2252 keeps its timing accuracy with input Slew Rates between 100V/ $\mu$ s and 4000V/ $\mu$ s of input Slew Rate.

The output stage drives tens of pF load capacitances without increased overshoot, but propagation delay increases about

1ns per 10pF. The output circuit is not a traditional TTL stage, and using an external pullup resistor will not change the  $V_{OH}$ . In general setting the output swing to TTL (by grounding the /TTL pin) will optimize overall propagation delay and  $\pm$ swing symmetry.

grounding the /TTL pin) will optimize overall propagation delay and  $\pm$ swing symmetry.
